

## Clinical trial results:

### Double blind crossover randomised controlled trial comparing letrozole versus clomifene citrate for ovulation induction in women with polycystic ovarian syndrome

#### Summary

EudraCT number	2006-006514-15
Trial protocol	GB
Global end of trial date	30 June 2014

#### Results information

Result version number	v1 (current)
This version publication date	16 March 2019
First version publication date	16 March 2019
Summary attachment (see zip file)	Double-blind randomized controlled trial of letrozole versus clomiphene citrate in subfertile women with polycystic ovarian syndrome (Amer et al Hum Reprod 2017.pdf)

Notes:

## Results analysis stage

Analysis stage	Final
Date of interim/final analysis	19 February 2016
Is this the analysis of the primary completion data?	Yes
Primary completion date	30 June 2014
Global end of trial reached?	Yes
Global end of trial date	30 June 2014
Was the trial ended prematurely?	No

Notes:

## General information about the trial

Main objective of the trial:

The main objective is to assess the efficacy of letrozole as an ovulation induction agent and to test the hypothesis that letrozole will generate better pregnancy rates than treatment with the current standard agent, clomifene citrate.

Protection of trial subjects:

This was a low risk trial. All participants were given contact numbers to call any time for any concerns.

Background therapy:

Nne

Evidence for comparator:

For decades, clomiphene citrate (CC) has been the standard first line ovulation induction (OI) agent in PCOS women with 85% ovulation rates and 40% pregnancy rates. This discrepancy between ovulation and conception rates has been attributed to the peripheral antioestrogenic actions of CC on endometrium and cervix.

Letrozole, an aromatase inhibitor that reduces oestrogen synthesis, has recently been considered as a potentially better alternative to CC. In contrast to CC, letrozole is not associated with any anti-oestrogenic effects on endometrium. This is supported by recent studies reporting adequate endometrial thickness during letrozole treatment. Furthermore, unlike CC that accumulates in the body because of its long half-life (two weeks), letrozole is rapidly eliminated due to its short half-life (45 hours), leading to late follicular rise in circulating oestrogen thereby enhancing endometrial development with subsequent increase in the chances of pregnancy. The rising oestrogen levels may also result in a shorter FSH window (mimicking the physiological cycle) with subsequent mono-ovulation and a lower risk of multiple pregnancy.

A Cochrane systematic review of clinical trials comparing aromatase inhibitors versus CC concluded that the quality of evidence in the reviewed trials was low due to poor reporting of study methods and possible publication bias. None of the reviewed trials was conducted in Europe. Furthermore, the only robust trial in that review included a high proportion of markedly obese women (Body mass Index (BMI)>40kg/m<sup>2</sup>), which does not reflect clinical practice in the majority of fertility centres worldwide (Legro et al, 2014). These results are therefore neither conclusive nor generalizable. The review concluded that further research is needed to compare letrozole with CC as a primary ovulation induction (OI) agent in PCOS women.

Actual start date of recruitment	25 April 2007
Long term follow-up planned	No
Independent data monitoring committee (IDMC) involvement?	No

## Subject disposition

### Recruitment

Recruitment details:

Participants were recruited at the fertility unit of Royal Derby Hospital between 25 April 2007 and 22 February 2013.

### Pre-assignment

Screening details:

A total of 202 women with anovulatory infertility due to PCOS were screened for eligibility, of whom 159 were randomized. the remaining 43 women were excluded due to not meeting inclusion criteria (n=25), declining to participate (n=8) or conceiving before recruitment (n=10).

### Period 1

Period 1 title	Randomisation
Is this the baseline period?	Yes
Allocation method	Randomised - controlled
Blinding used	Double blind
Roles blinded	Subject, Investigator, Monitor, Data analyst

Blinding implementation details:

The two medicines investigated in the trial were prepared in identical capsules and provided in identical packages (as explained above). Throughout the study, the patient and the investigator remained blinded to the treatment. Investigators carrying out the monitoring, assessment of response to treatment and data analysis were kept blinded. The dispenser of the medicine kept the identifying tear-off label of each pack to allow unblinding at any time if necessary.

### Arms

Are arms mutually exclusive?	Yes
<b>Arm title</b>	Arm A: Clomifene

Arm description:

79 Participants allocated to clomiphene citrate

Arm type	Active comparator
Investigational medicinal product name	Clomiphene citrate
Investigational medicinal product code	
Other name	Clomifene citrate
Pharmaceutical forms	Tablet
Routes of administration	Oral use

Dosage and administration details:

Clomiphene citrate was given orally daily for five days in the early follicular phase from day 2 to day 6 of a spontaneous menstrual period or a withdrawal bleed induced by progestogen administration. The starting daily dose was one capsule 50 mg. Patients were monitored for ovulation by follicle tracking (using ultrasound) and measurement of serum concentration of progesterone in mid-luteal phase. If the patient did not ovulate on one capsule the dose would be increased in the second cycle to two capsules a day (i.e. 100 mg/day). Once ovulation had been achieved on a certain dose, treatment would be continued until pregnancy is achieved or for up to 6 cycles.

<b>Arm title</b>	Arm B: letrozole
------------------	------------------

Arm description:

80 Participants allocated to letrozole

Arm type	Experimental
Investigational medicinal product name	Letrozole
Investigational medicinal product code	
Other name	
Pharmaceutical forms	Tablet
Routes of administration	Oral use

#### Dosage and administration details:

Letrozole was given orally daily for five days in the early follicular phase from day 2 to day 6 of a spontaneous menstrual period or a withdrawal bleed induced by progestogen administration. The starting daily dose was one capsule 2.5 mg. Patients were monitored for ovulation by follicle tracking (using ultrasound) and measurement of serum concentration of progesterone in mid-luteal phase. If the patient did not ovulate on one capsule the dose would be increased in the second cycle to two capsules a day (i.e. 5 mg/day). Once ovulation had been achieved on a certain dose, treatment would be continued until pregnancy is achieved or for up to 6 cycles.

Number of subjects in period 1	Arm A: Clomifene	Arm B: letrozole
Started	79	80
Completed	74	75
Not completed	5	5
Consent withdrawn by subject	-	2
Pregnancy	2	2
Lost to follow-up	3	1

#### Period 2

Period 2 title	Cross-over
Is this the baseline period?	No
Allocation method	Randomised - controlled
Blinding used	Double blind
Roles blinded	Subject, Investigator, Monitor, Data analyst

#### Blinding implementation details:

The two medicines investigated in the trial were prepared in identical capsules and provided in identical packages (as explained above). Throughout the study, the patient and the investigator remained blinded to the treatment. Investigators carrying out the monitoring, assessment of response to treatment and data analysis were kept blinded. The dispenser of the medicine kept the identifying tear-off label of each pack to allow unblinking at any time if necessary.
