Results analysis stage

Analysis stage	Final
Date of interim/final analysis	20 April 2017
Is this the analysis of the primary completion data?	Yes
Primary completion date	18 January 2017
Global end of trial reached?	Yes
Global end of trial date	18 January 2017
Was the trial ended prematurely?	No

Notes:

General information about the trial

Main objective of the trial:

Does the addition of 14 days rifampicin to initial standard antibiotic therapy reduce bacteriological failure/death through 12 weeks from randomisation in adults with *Staphylococcus aureus* bacteraemia?

Protection of trial subjects:

A Data Monitoring Committee (DMC) was established. The DMC could recommend premature closure or reporting of the trial, or that recruitment be discontinued or modified.

Background therapy:

Despite scant data from controlled trials, current treatment guidelines recommend that *S. aureus* bacteraemia should be treated with at least 14 days of an intravenous (IV) beta-lactam antibiotic, or a glycopeptide if the bacteria are methicillin-resistant. Combination antimicrobial therapy is generally not recommended, except in severe methicillin-resistant *S. aureus* (MRSA) infections (e.g. endocarditis, prosthetic joint infections). Most of the recommendations are based on uncontrolled observational studies and clinical experience, and views of how to manage *S. aureus* bacteraemia differ widely.

To estimate the degree of uncertainty around clinical practice within the NHS we conducted a multi-centre, prospective observational study of patients with *S. aureus* bacteraemia. The findings from the first year (November 2008-2009; 549 cases) revealed that management varied widely among NHS Trusts, with little adherence to the published guidelines. Centres varied significantly ($p < 0.01$) in the proportions given oral treatment alone for $> 50\%$ of treatment (range 12-40% across NHS Trusts), in those treated for longer than 28 days (range 13-54%), and in those given combination antimicrobial therapy (range 14-94%). Twenty four percent of patients died during admission, 72% within the first 14 days of treatment. Older age, longer time in hospital before bacteraemia, and an unidentified infection focus were independent predictors of in-hospital death ($p < 0.001$).

Our literature review and observational study confirm *S. aureus* to be a common, frequently fatal blood infection within NHS Hospitals - yet the optimal management remains uncertain and practice highly variable. In particular, key questions concerning the most effective antimicrobial regimen are unanswered, and will remain so until they have been addressed by large, well-conducted RCTs. For reasons described below, one major clinical research priority is to assess the role of adjuvant antibiotic therapy.

Evidence for comparator:

Three properties make rifampicin an attractive, if unproven, antibiotic for *S. aureus* bacteraemia treatment. First, it has good oral bioavailability. Second, it penetrates cells, tissues, and biofilms better than beta-lactam and glycopeptide antibiotics (the current mainstays of *S. aureus* bacteraemia treatment) and, therefore, in combination with these agents, may resolve serious *S. aureus* infections faster and more effectively. And third, it is cheap: a daily 600mg dose costs £0.73 by mouth and £7.67 intravenously.

There are three important potential problems with using rifampicin for the treatment of *S. aureus* bacteraemia: the development of rifampicin resistant bacteria, interactions with other drugs, and hepatic toxicity. Resistance can be acquired rapidly when rifampicin is used alone in treatment, resulting from mutations in the drug's binding site (the β -subunit of the bacterial DNA-dependent RNA polymerase). Interactions with other drugs are mediated by rifampicin's ability to increase their metabolism through the potent induction of the hepatic cytochrome p450 system. Lastly, rifampicin can cause hepatic toxicity, although the enormous worldwide experience of using rifampicin for the prevention and 6-month treatment of tuberculosis confirms the drug is extremely well-tolerated and causes clinically significant hepatitis in $< 1\%$ of patients.

Actual start date of recruitment	10 December 2012
Long term follow-up planned	No
Independent data monitoring committee (IDMC) involvement?	Yes

Notes:

Population of trial subjects

Subjects enrolled per country

Country: Number of subjects enrolled	United Kingdom: 758
Worldwide total number of subjects	758
EEA total number of subjects	758

Notes:

Subjects enrolled per age group

In utero	0
Preterm newborn - gestational age < 37 wk	0
Newborns (0-27 days)	0
Infants and toddlers (28 days-23 months)	0
Children (2-11 years)	0
Adolescents (12-17 years)	0
Adults (18-64 years)	376
From 65 to 84 years	313
85 years and over	69

Subject disposition

Recruitment

Recruitment details:

Adults (≥ 18 years) were recruited from 29 hospitals from around the United Kingdom. Subjects were recruited by the study team and in consultation with the hospital team responsible for the patient's in-hospital care. Subjects, or their legal representatives (in the case of incapacity), gave written informed consent. Main eligibility criteria below.

Pre-assignment

Screening details:

INCLUSION CRITERIA

S aureus (meticillin-susceptible/resistant) grown from ≥ 1 blood culture

<96h active antibiotic therapy for current infection, not including rifampicin

EXCLUSION CRITERIA

Infection not caused by *S aureus* alone

Sensitivity results already available and demonstrate rifampicin resistant *S aureus*

Rifampicin contraindicated

TB

Pre-assignment period milestones

Number of subjects started	2884 ^[1]
Number of subjects completed	758

Pre-assignment subject non-completion reasons

Reason: Number of subjects	Non-randomisation: 2126
----------------------------	-------------------------

Notes:

[1] - The number of subjects reported to have started the pre-assignment period are not the same as the worldwide number enrolled in the trial. It is expected that these numbers will be the same.

Justification: 2884 subjects were screened, but 758 randomised.

Period 1

Period 1 title	Overall trial (overall period)
Is this the baseline period?	Yes
Allocation method	Randomised - controlled
Blinding used	Double blind
Roles blinded	Subject, Investigator, Monitor, Carer, Assessor

Blinding implementation details:

Rifampicin can turn urine orange-red. This is variable both within and between subjects, but a potential source of unblinding, particularly of subjects. The opportunity for doctors/nurses to examine urine at the bedside only occurred in subjects with catheters, removed at the earliest opportunity.

Rifampicin capsules were overencapsulated to make them indistinguishable from placebo. In those needing IV treatment, pharmacists dispensed rifampicin for infusion or saline, with an opaque cover.

Arms

Are arms mutually exclusive?	Yes
Arm title	Placebo

Arm description:

Treatment with placebo for 14 days from randomisation (oral and/or IV according to patient status) (plus standard backbone antibiotic therapy as chosen by the physician):

Placebo oral 300 mg capsules containing cellulose

Standard saline for intravenous injection

Additional intravenous catheters were not required to administer the study drug as standard antibiotic therapy (with a beta-lactam or glycopeptide) is always given intravenously.

The dose of placebo was prescribed according to the patient's weight:

those <60kg received 600mg every 24h
those ≥60kg received 900mg every 24h

Oral doses could be given once or twice daily, according to clinician and patient preference. If taken twice daily, 900mg daily (3 capsules) was taken as unequal divided doses (600mg am, 300mg pm). The study treatment was given for 14 days, unless fewer than 14 days of standard antibiotic therapy was planned, in which case placebo was given until standard antibiotic treatment ended.

Arm type	Placebo
Investigational medicinal product name	Placebo
Investigational medicinal product code	
Other name	
Pharmaceutical forms	Capsule, Solution for infusion
Routes of administration	Intravenous use, Oral use

Dosage and administration details:

Placebo was given by oral or intravenous route, according to the attending physician's preference and the patient's status. Additional intravenous catheters were not required to administer the study drug as standard antibiotic therapy (with a beta-lactam or glycopeptide) is always given intravenously. Patients may start taking IV placebo and then move to the oral formulation when they could swallow safely. We anticipated around 90% of doses would be given by mouth.

Arm title	Rifampicin
------------------	------------

Arm description:

Active treatment with rifampicin for 14 days from randomisation (oral and/or IV according to patient status) (plus standard antibiotic):

Rifampicin oral 300 mg capsules
Rifampicin 600 mg for intravenous injection

Additional intravenous catheters were not required to administer the study drug as standard antibiotic therapy is always given intravenously.

The dose of rifampicin was prescribed according to the patient's weight:

those <60kg received 600mg every 24h
those ≥60kg received 900mg every 24h

Oral doses could be given once or twice daily, according to clinician and patient preference. If taken twice daily, 900mg daily (3 capsules) was taken as unequal divided doses (600mg am, 300mg pm): as rifampicin can also be taken once daily, this provided adequate exposure. The study treatment was given for 14 days, unless fewer than 14 days of standard antibiotic therapy was planned, in which case rifampicin was given until standard antibiotic treatment ended.

Arm type	Experimental
Investigational medicinal product name	Rifampicin
Investigational medicinal product code	
Other name	Rifampin
Pharmaceutical forms	Capsule, Powder for concentrate for solution for infusion
Routes of administration	Intravenous use, Oral use

Dosage and administration details:

Rifampicin was given by oral or intravenous route, according to the attending physician's preference and the patient's status. Oral rifampicin has excellent bioavailability with oral administration achieving comparable plasma concentrations to the intravenous route. Therefore, provided a patient can swallow safely, most physicians will elect to use rifampicin orally. We anticipated around 90% of doses would be given by mouth. Patients may start taking IV rifampicin and then move to the oral formulation when they could swallow safely.

It is important, however, to allow intravenous administration to very sick patients who may not be able to swallow or absorb tablets. Additional intravenous catheters were not required to administer the study drug as standard antibiotic therapy (with a beta-lactam or glycopeptide) is always given intravenously.

Number of subjects in period 1	Placebo	Rifampicin
Started	388	370
Completed	360	333
Not completed	28	37
Consent withdrawn by subject	7	15
Lost to follow-up	21	22

End points

End points reporting groups

Reporting group title	Placebo
-----------------------	---------

Reporting group description:

Treatment with placebo for 14 days from randomisation (oral and/or IV according to patient status) (plus standard backbone antibiotic therapy as chosen by the physician):

Placebo oral 300 mg capsules containing cellulose
Standard saline for intravenous injection

Additional intravenous catheters were not required to administer the study drug as standard antibiotic therapy (with a beta-lactam or glycopeptide) is always given intravenously.

The dose of placebo was prescribed according to the patient's weight:

those <60kg received 600mg every 24h
those ≥60kg received 900mg every 24h

Oral doses could be given once or twice daily, according to clinician and patient preference. If taken twice daily, 900mg daily (3 capsules) was taken as unequal divided doses (600mg am, 300mg pm). The study treatment was given for 14 days, unless fewer than 14 days of standard antibiotic therapy was planned, in which case placebo was given until standard antibiotic treatment ended.

Reporting group title	Rifampicin
-----------------------	------------

Reporting group description:

Active treatment with rifampicin for 14 days from randomisation (oral and/or IV according to patient status) (plus standard antibiotic):

Rifampicin oral 300 mg capsules
Rifampicin 600 mg for intravenous injection

Additional intravenous catheters were not required to administer the study drug as standard antibiotic therapy is always given intravenously.

The dose of rifampicin was prescribed according to the patient's weight:

those <60kg received 600mg every 24h
those ≥60kg received 900mg every 24h

Oral doses could be given once or twice daily, according to clinician and patient preference. If taken twice daily, 900mg daily (3 capsules) was taken as unequal divided doses (600mg am, 300mg pm): as rifampicin can also be taken once daily, this provided adequate exposure. The study treatment was given for 14 days, unless fewer than 14 days of standard antibiotic therapy was planned, in which case rifampicin was given until standard antibiotic treatment ended.

Primary: Bacteriological failure

End point title	Bacteriological failure
-----------------	-------------------------

End point description:

In the protocol, bacteriological failure is defined as death or microbiologically confirmed treatment failure or disease recurrence.

Microbiologically confirmed treatment failure is defined as symptoms and signs of infection for longer than 14 days from randomisation with the isolation of the same strain of *S. aureus* (confirmed by genotyping) from a sterile site. Disease recurrence is defined as the isolation of the same strain of *S. aureus* from a sterile site after at least 7 days of apparent clinical improvement. The same strain will be defined as one with the same genotype by multi-locus sequence and spa-typing.

Because of failure to locate bacteriological isolates/missing samples, the primary analysis of the primary endpoint includes all bacteriological failures/recurrences confirmed by the Endpoint Review Committee and a secondary analysis counts as events only those with samples and the same genotype by whole

genome sequencing and spa-typing (or who died).

End point type	Primary
