## General information about the trial

Main objective of the trial:

This study aims to assess the acceptability and feasibility of using a simple treatment with tablets (metformin) for women with mild gestational diabetes. Metformin is safe in pregnancy and has the advantage that frequent blood glucose monitoring is not necessary. We hope this treatment will be effective in reducing the number of babies which gain excessive weight in pregnancy, without the need for frequent hospital visits and high intervention rates which are associated with the intensive antenatal care routinely offered to women with gestational diabetes.

Protection of trial subjects:

Metformin is associated with a number of gastrointestinal side effects and women unable to tolerate the drug will be advised to discontinue (<5% from previous studies). Although metformin treatment aims to reduce blood glucose levels before and after eating, serious hypoglycaemia is very uncommon and metformin is prescribed in several settings without regular blood glucose monitoring. Women randomised to the diabetic antenatal care arm of the study will be asked to perform regular blood glucose monitoring (BGM). This is an onerous task for women in pregnancy but is standard practice within diabetic antenatal clinics. Women who have HBGM outside the target range will be prescribed metformin and those who do not meet target control with metformin will be prescribed adjuvant insulin. This prescribing regime will be in line with current prescribing practices within our hospital. Women in this arm of the study will also be offered monthly ultrasound scans to assess fetal growth. It is usual practice to offer induction of labour to women with a macrosomic fetus (>95th centile) and therefore some women in this group will be offered additional obstetric interventions. Metformin can sometimes cause some stomach upset (sickness and diarrhoea) so the dose will be increased slowly to minimise this side effect. Metformin can also cause taste disturbance and affect appetite. There is a very rare (<1/10,000), but serious side effect of metformin called 'lactic acidosis'. This occurs in individuals with kidney or liver problems. We will perform a blood test at the beginning of the study to ensure that you do not have any liver or kidney problems before you start the metformin tablets to ensure that the treatment is safe for you. Other very rare side effects include skin rashes.

Background therapy:

Standard diabetes antenatal care (NICE diabetes guidelines) with HBGM and scan surveillance.

Evidence for comparator:

The pregnancy outcomes for all women, delivered at St Mary's Hospital Manchester in 2010, who had an oral glucose tolerance test (OGTT) which would fit the proposed IADPSG diagnostic criteria, have recently been reviewed. 4% of all women who had an OGTT had isolated mild fasting hyperglycaemia (fasting 5.1-5.4 mmol/L; 2 hour <8.5mmol/L). All of these women were managed in normal antenatal clinics with no treatment. The frequency of large for gestational age babies (LGA) in this group (defined as >95th centile using centiles adjusted for maternal characteristics, fetal gender and gestation) was 16.4% (95% CI 9.0-27.8%), more than three times the expected frequency. In addition, we have analysed the Manchester data collected as part the HAPO study (n=2388). In this cohort, 201 women (8%) had a fasting blood glucose level between 5.1 and 5.4 mmol/L (normal 2 hour; <8.5mmol/L). The frequency of LGA (>95th centile) in this group was 9.0% compared to 3.9% (p=0.002) in the normoglycaemic group (n=1886) (OR 2.2 (95% CI 1.4-3.3). This data also suggests that the frequency of macrosomic infants delivered to women with mild degrees of fasting hyperglycaemia in the third trimester is unacceptably high. It is therefore timely to determine whether a simple intervention in this group could reduce the number of macrosomic infants delivered. This pilot study will assess the acceptability of metformin, prescribed in conjunction with routine antenatal care, compared to a standard diabetic model of antenatal care. In the study arm, metformin will be titrated up to the maximum tolerated dose in the absence of home blood glucose monitoring (HBGM). Women in the standard diabetic clinic arm will have their treatment titrated according to HBGM with the addition of insulin where blood glucose levels are out of target, this will allow us to make an assessment of the effectiveness of metformin in this group of women with mild fasting hyperglycaemia.

Actual start date of recruitment	02 December 2013
Long term follow-up planned	No
Independent data monitoring committee (IDMC) involvement?	No

Notes:

---

## Population of trial subjects

---

### Subjects enrolled per country

---

Country: Number of subjects enrolled	United Kingdom: 40
Worldwide total number of subjects	40
EEA total number of subjects	40

Notes:

---

### Subjects enrolled per age group

---

In utero	0
Preterm newborn - gestational age < 37 wk	0
Newborns (0-27 days)	0
Infants and toddlers (28 days-23 months)	0
Children (2-11 years)	0
Adolescents (12-17 years)	0
Adults (18-64 years)	40
From 65 to 84 years	0
85 years and over	0

## Subject disposition

### Recruitment

Recruitment details:

Over the course of this study we aim to recruit 60 women.

### Pre-assignment

Screening details:

Women with risk factors for GDM (NICE 2008) will be offered an oral glucose tolerance test (OGTT) at 26 weeks gestation as part of their routine antenatal care. Women with mild GDM (Fasting 5.1mmol/l- 5.4 mmol/L; 2-hour <8.5 mmol/l) will be recruited into the study.

### Period 1

Period 1 title	Overall trial (overall period)
Is this the baseline period?	Yes
Allocation method	Randomised - controlled
Blinding used	Not blinded

### Arms

Are arms mutually exclusive?	Yes
<b>Arm title</b>	Metformin

Arm description:

Women randomised to the study arm (Metformin only treatment arm) will be prescribed metformin tablets up to 2000mg from randomisation (26-28 weeks gestation) and will stop once they have delivered their baby.

Women will be asked to start with 500mg metformin (1 tablet, Once Daily) taken with food, increasing on Day 4 by an increment of 500mg per day (in other words to 1 tablet, twice daily). Day 7: a further increment of 500mg per day (in other words to 1 tablet, three times daily). On Day 14, women will increase the evening dose of metformin by a further 500mg. If side effects (largely anticipated to be gastro-intestinal) are experienced, the woman should drop to the previous dose or 500mg metformin (whichever is the greater) and wait for 3 days before increasing the dosage again. The maximum recommended dose is 2000mg daily, taken as three divided doses. The usual starting dose is one tablet 2 or 3 times daily given during or after meals.

Arm type	Experimental
Investigational medicinal product name	Metformin
Investigational medicinal product code	
Other name	
Pharmaceutical forms	Coated tablet
Routes of administration	Oral use

Dosage and administration details:

Women randomised to the study arm (Metformin only treatment arm) will be prescribed metformin tablets up to 2000mg from randomisation (26-28 weeks gestation) and will stop once they have delivered their baby.

Women will be asked to start with 500mg metformin (1 tablet, Once Daily) taken with food, increasing on Day 4 by an increment of 500mg per day (in other words to 1 tablet, twice daily). Day 7: a further increment of 500mg per day (in other words to 1 tablet, three times daily). On Day 14, women will increase the evening dose of metformin by a further 500mg. If side effects (largely anticipated to be gastro-intestinal) are experienced, the woman should drop to the previous dose or 500mg metformin (whichever is the greater) and wait for 3 days before increasing the dosage again. The maximum recommended dose is 2000mg daily, taken as three divided doses. The usual starting dose is one tablet 2 or 3 times daily given during or after meals.

<b>Arm title</b>	Standard care
------------------	---------------

Arm description:

In addition to dietary advice and lifestyle advice, women in the standard care arm will be issued with a HBGM meter and asked to record capillary blood glucose before and 1 hour after meals (x 7/day) with target glucose ranges of fasting <5.5 and 1 hour post prandial <7.8mmol/L. Women will be provided

with a contact telephone number and asked to contact the research midwife if the blood sugars are outside the target range on 3 or more occasions within one week. The handheld maternity records will be updated to inform health care professionals that the woman is participating in the trial and has been randomised to the standard care arm. A baseline ultrasound to assess fetal growth will be performed at study visit 1. Women will be reviewed in the research clinic 2 weeks after their initial appointment.

## Adverse events

### Adverse events information

Timeframe for reporting adverse events:

The occurrence of adverse events will be sought by non-directive questioning of the patient during the study. Adverse events also may be detected when they are volunteered by the patient.

Assessment type	Non-systematic

### Reporting groups

Reporting group title	Metformin
-----------------------	-----------

Reporting group description:

Women randomised to the study arm (Metformin only treatment arm) will be prescribed metformin tablets up to 2000mg from randomisation (26-28 weeks gestation) and will stop once they have delivered their baby.

Women will be asked to start with 500mg metformin (1 tablet, Once Daily) taken with food, increasing on Day 4 by an increment of 500mg per day (in other words to 1 tablet, twice daily). Day 7: a further increment of 500mg per day (in other words to 1 tablet, three times daily). On Day 14, women will increase the evening dose of metformin by a further 500mg. If side effects (largely anticipated to be gastro-intestinal) are experienced, the woman should drop to the previous dose or 500mg metformin (whichever is the greater) and wait for 3 days before increasing the dosage again. The maximum recommended dose is 2000mg daily, taken as three divided doses. The usual starting dose is one tablet 2 or 3 times daily given during or after meals.

Reporting group title	Standard care
-----------------------	---------------

Reporting group description:

In addition to dietary advice and lifestyle advice, women in the standard care arm will be issued with a HBGM meter and asked to record capillary blood glucose before and 1 hour after meals (x 7/day) with target glucose ranges of fasting <5.5 and 1 hour post prandial <7.8mmol/L. Women will be provided with a contact telephone number and asked to contact the research midwife if the blood sugars are outside the target range on 3 or more occasions within one week. The handheld maternity records will be updated to inform health care professionals that the woman is participating in the trial and has been randomised to the standard care arm. A baseline ultrasound to assess fetal growth will be performed at study visit 1. Women will be reviewed in the research clinic 2 weeks after their initial appointment.

Serious adverse events	Metformin	Standard care	
Total subjects affected by serious adverse events			
subjects affected / exposed	1 / 20 (5.00%)	0 / 20 (0.00%)

## More information

### Substantial protocol amendments (globally)

Were there any global substantial amendments to the protocol? Yes

Date	Amendment
19 October 2014	SA01 - TBC - need summary of changes

Notes:

---

### Interruptions (globally)

Were there any global interruptions to the trial? No

### Limitations and caveats

Limitations of the trial such as small numbers of subjects analysed or technical problems leading to unreliable data.

None.
