

Patient intra-observer reproducibility for each scan time was 100%. Similarly, the intra-observer reproducibility on a lesion basis was equal to 100%, therefore the fraction of the diagnosis between first and second reading for all index lesions at each scan time-point was equal to 100% for each observer. This result is excellent demonstrating that the confidence in the interpretation of images for a single observer is high both in the case of first reading and second reading.
