Paediatric regulatory details

Is trial part of an agreed paediatric investigation plan (PIP)	No
Does article 45 of REGULATION (EC) No 1901/2006 apply to this trial?	No
Does article 46 of REGULATION (EC) No 1901/2006 apply to this trial?	No

Notes:

Results analysis stage

Analysis stage	Final
Date of interim/final analysis	13 September 2018
Is this the analysis of the primary completion data?	Yes
Primary completion date	13 September 2018
Global end of trial reached?	Yes
Global end of trial date	13 September 2018
Was the trial ended prematurely?	Yes

Notes:

General information about the trial

Main objective of the trial:

The primary objective is to achieve the double composite endpoint of a reduction in HbA1c ($\geq 0.3\%$) and weight loss ($\geq 1\text{kg}$) 3-4 weeks post-Ramadan.

Protection of trial subjects:

All study participants were required to read a patient Information Sheet (PIS) about the trial (including trial treatments and any known side-effects) and sign an Informed Consent Form (ICF). Patients were monitored regularly throughout the trial duration.

Background therapy:

Patients taking monotherapy (Metformin) or standard second line therapy (Metformin plus other glucose lowering therapy (comparator)) were recruited into the trial.

Evidence for comparator:

There have been significant advances in glucose lowering therapies in T2DM and their availability, thus offering a greater choice of therapies to people with diabetes with the potential for supporting safer fasting. Three new classes of therapy have been licensed for the treatment of T2DM in the UK in the past 10 years. The most recent class that has been introduced are the Sodium Glucose Co-Transporter 2 Inhibitors (SGLT2 inhibitors).

Canagliflozin (Invokana™) is one of a number of SGLT2 inhibitors that have been licensed within the UK. Phase III trials of this novel agent have reported reductions in HbA1c, body weight and systolic blood pressure reduction. Canagliflozin has a low intrinsic propensity to cause hypoglycaemia. Importantly this drug is reported to be well-tolerated and has a good safety profile in patients with inadequately controlled T2DM, as monotherapy or in combination with other glucose lowering therapy including sulphonylureas and metformin.

Exploration in advent of novel therapies such as Canagliflozin which could potentially provide positive health outcomes to those who wish to participate in Ramadan is required.

The aim in the present study was to determine if the addition of Canagliflozin therapy to monotherapy of metformin was more effective at achieving the double composite endpoint of a reduction in HbA1c ($\geq 0.3\%$) and weight loss ($\geq 1\text{kg}$) 3-4 weeks post-Ramadan. Patients currently on dual therapy (specifically metformin plus a sulphonylurea or pioglitazone or repaglinide or DPP-4 inhibitor) were included to determine whether switching to metformin plus Canagliflozin is more effective at achieving the composite endpoint compared to those remaining on previous dual therapy.

Actual start date of recruitment	15 August 2016
Long term follow-up planned	No
Independent data monitoring committee (IDMC) involvement?	Yes

Notes:

Population of trial subjects

Subjects enrolled per country

Country: Number of subjects enrolled	United Kingdom: 25
--------------------------------------	--------------------

Worldwide total number of subjects	25
EEA total number of subjects	25

Notes:

Subjects enrolled per age group	
In utero	0
Preterm newborn - gestational age < 37 wk	0
Newborns (0-27 days)	0
Infants and toddlers (28 days-23 months)	0
Children (2-11 years)	0
Adolescents (12-17 years)	0
Adults (18-64 years)	22
From 65 to 84 years	3
85 years and over	0

Subject disposition

Recruitment

Recruitment details:

Sponsor Greenlight was issued on 11/07/2016. The First Patient First Visit (FPFV) date was 15/08/2016 and the Last Patient Last Visit (LPLV) date was 13/09/2018. Participants took part in the study at one of two sites in the UK (Leicester and Birmingham).

Pre-assignment

Screening details:

Participants with Type 2 Diabetes Mellitus planning to fast during Ramadan were enrolled. Participants on monotherapy at entry were randomised 1:1 to metformin + Canagliflozin or metformin + other glucose lowering therapy. Participants on dual therapy at entry were randomised 1:1 to metformin + Canagliflozin or to existing dual therapy combination

Period 1

Period 1 title	Overall trial (overall period)
Is this the baseline period?	Yes
Allocation method	Randomised - controlled
Blinding used	Not blinded

Blinding implementation details:

N/A

Arms

Are arms mutually exclusive?	Yes
Arm title	Study Drug (IMP)

Arm description:

Canagliflozin (Invokana™) 100mg or 300mg, orally, once daily.

Arm type	Experimental
Investigational medicinal product name	Canagliflozin (Invokana™)
Investigational medicinal product code	
Other name	
Pharmaceutical forms	Tablet
Routes of administration	Oral use

Dosage and administration details:

There was a lead-in period for this study of 4 weeks to ensure that the correct dose was achieved for each participant. Titration of study treatment Canagliflozin (Invokana™) oral hyperglycaemic agent began with a starting dose of 100mg once daily. Those participants that tolerated this dose well for 14 days +/- 3 days had this increased to 300mg once daily by telephone consultation. The best tolerated dose was then maintained until the participant's final study visit. Conversely, if participants experienced tolerability issues such as recurrent hypoglycaemia or postural hypotension or they exceeded the HbA1c target, they did not have the study treatment titrated.

Arm title	Comparator (other glucose lowering therapy)
------------------	---

Arm description:

Standard second-line therapy (a sulphonylurea or pioglitazone or repaglinide or DPP-4 inhibitor) in line with NICE guidelines as the preferred second-line therapy after metformin.

Arm type	Active comparator
Investigational medicinal product name	Sulphonylurea
Investigational medicinal product code	
Other name	Gliclazide and glimepiride
Pharmaceutical forms	Tablet
Routes of administration	Oral use

Dosage and administration details:

Gliclazide and glimepiride were the sulphonylureas chosen to be prescribed to participants in this study. Gliclazide dose was started at 40-80 mg once daily, up to maximum dose of 160mg twice daily. Glimepiride was initially administered as 1mg once daily, up to a maximum dose of 4mg once daily.

Investigational medicinal product name	Repaglinide
Investigational medicinal product code	
Other name	
Pharmaceutical forms	Tablet
Routes of administration	Oral use

Dosage and administration details:

An initial dose of 0.5mg once daily where no prior treatment has been given was prescribed. However, where prior treatment was in place, an initial dose of 1-2mg once daily was started and this was titrated up to a maximum dose of 4mg daily.

Investigational medicinal product name	Pioglitazone
Investigational medicinal product code	
Other name	
Pharmaceutical forms	Tablet
Routes of administration	Oral use

Dosage and administration details:

An initial dose of 15mg or 30mg once daily was prescribed. If the response was inadequate, the maximum daily dosage was increased to 45mg once daily.

Investigational medicinal product name	DPP4 inhibitor
Investigational medicinal product code	
Other name	Sitagliptin, Vildagliptin, Saxagliptin
Pharmaceutical forms	Tablet
Routes of administration	Oral use

Dosage and administration details:

The study clinicians did not actively prescribe DPP-4 inhibitors. If participants were taking metformin and a DPP-4 inhibitor at baseline and were randomised to continuation of their current prescribed second line therapy (control arm), they remained on a DPP-4 inhibitor. If they were randomised to the intervention arm, they were prescribed metformin and Canagliflozin (Invokana™).

Primary: Reduction in HbA1c and weight 3-4 weeks post-Ramadan

End point title	Reduction in HbA1c and weight 3-4 weeks post-Ramadan ^[1]
End point description: The primary outcome is the achievement of the double composite endpoint of a reduction in HbA1c (at least 0.3%) and weight loss (of at least 1kg) 3-4 weeks post-Ramadan.	
End point type	Primary
End point timeframe: 3-4 weeks post Ramadan.	

Notes:

[1] - No statistical analyses have been specified for this primary end point. It is expected there is at least one statistical analysis for each primary end point.

Justification: 50% of participants on Canagliflozin (IMP) achieved planned primary outcome compared to 12.5% on standard second line therapy (control). Underpowered to test statistical significance of this trend.

End point values	Study Drug (IMP)	Comparator (other glucose lowering therapy)

Adverse events

Adverse events information

Timeframe for reporting adverse events:

Consent to last dose of drug.

Adverse event reporting additional description:

At each visit, the investigator documented adverse events and abnormal laboratory findings. Any event spontaneously reported by the participant or observed by the investigator was recorded, irrespective of relation to study treatment. All SAEs and non-serious AEs classified as severe or possibly/probably related were followed up until resolution.

Assessment type	Systematic

More information

Substantial protocol amendments (globally)

Were there any global substantial amendments to the protocol? Yes

Date	Amendment
18 April 2016	Following the receipt of a Direct Healthcare Professional Communication report (dated 21st March 2016) regarding the risk of diabetic ketoacidosis (DKA) during treatment with SGLT2-inhibitors including Canagliflozin, the study team updated the protocol to include additional exclusion criteria, revised the treatment management sub-section, and revised the expected serious adverse events/reactions sub-section. Further, the study team revised timelines throughout the protocol to indicate a study extension of 3-4 months (recruitment phase extended to April 2017 but follow-up period reduced from 12 months to 3 months) to enable the LPLV in September 2017.
14 November 2016	<p>Exclusion criteria revised to include 1) Any contraindication to the IMP 2) individuals on loop diuretics.</p> <p>The study team added an ALT blood test at baseline to assess eligibility (12. Impaired liver function (ALT \geq 2.5 times upper limit of normal)). Further, the study team included some treatment management information about lower limbs and AKI in the treatment section of the protocol (following the recent safety updates) and included AKI in the expected SAE/SAR section of the protocol (in line with updated SmPC).</p>
27 June 2017	<p>The study team extended the study timelines to enable an extended recruitment period (proposed recruitment end date: April 2018) to aid the study team to recruit participants to time and target. Further, the inclusion/exclusion criteria were revised to aid recruitment following a high screen failure rate in the previous recruitment phase. HbA1c ranges were widened, the requirement to fast for 10 consecutive days was removed, and participants taking DPP-4 inhibitors were included. The study team revised the wording within the protocol (randomisation & code breaking, study design and statistical methods) about stratification to include DPP-4 inhibitors. Specifically, randomisation was carried out using block design and stratified by site (Leicester and Birmingham) and entry therapy (monotherapy, dual therapy not including DPP-4 inhibitor, and dual therapy including DPP-4 inhibitor). Participants with monotherapy at entry were randomised 1:1 to metformin + Canagliflozin (Invokana™) or to metformin + a sulphonylurea or repaglinide or pioglitazone; whilst participants with dual therapy at entry were randomised 1:1 to metformin + Canagliflozin (Invokana™) or to existing dual therapy combination.</p> <p>Finally the study team included some additional information for Repaglinide under the treatment section of the protocol following the SmPC review. In an interaction study with healthy volunteers, co-administration of clopidogrel (300 mg loading dose), a CYP2C8 inhibitor, increased repaglinide exposure (AUC_{0-∞}) 5.1-fold and continued administration (75 mg daily dose) increased repaglinide exposure (AUC_{0-∞}) 3.9-fold. A small, significant decrease in blood glucose values was observed. Since the safety profile of the co-treatment had not been established in these patients, the concomitant use of clopidogrel and repaglinide were avoided.</p>
19 February 2018	Notification to the MHRA from the Chief Investigator about the decision to terminate recruitment of participants into the trial. This decision was made solely due to practical issues/challenges with recruitment. All patients enrolled into the study at that time and receiving treatment were followed-up until September 2018.

Notes:

Interruptions (globally)

Were there any global interruptions to the trial? Yes

Date	Interruption	Restart date
19 February 2018	Despite the study team's success with a previous Ramadan study and ongoing engagement with our local communities, the 'Can Do Ramadan' study team faced many challenges with recruitment (including changes to local prescribing practice) and the study did not achieve its recruitment target, culminating in its early closure having only recruited 21.5% of the recruitment target. After much deliberation, the Chief Investigator and Senior Management team took the decision to stop actively recruiting to the 'Can Do Ramadan' study but to continue to follow-up the actively participating participants (up until September 2018), resulting in descriptive analysis of the main study data.	-

Notes:

Limitations and caveats

Limitations of the trial such as small numbers of subjects analysed or technical problems leading to unreliable data.

Despite the study team's success with a previous Ramadan study and engagement with local communities, the team faced many challenges with recruitment and the study did not achieve its recruitment target, culminating in its early closure.

Notes:
