

Clinical trial results:

A multi-center, randomized, subject and investigator blinded, placebo-controlled, active comparator, parallel group proof of concept study to evaluate the efficacy, safety, tolerability, and pharmacokinetics of MIJ821 in patients with treatment-resistant depression

Notes:

General information about the trial

Main objective of the trial:

The primary objective was to assess efficacy of MIJ821 in treatment-resistant depression.

Protection of trial subjects:

The study was in compliance with the ethical principles derived from the Declaration of Helsinki and the International Conference on Harmonization (ICH) Good Clinical Practice (GCP) guidelines. All the local regulatory requirements pertinent to safety of trial subjects were also followed during the conduct of the trial.

Recruitment

Recruitment details: -

Pre-assignment

Screening details:

Overall, 72 subjects were randomized in this study, and 2 of them discontinued from study before receiving any study treatment. All the 70 treated subjects were included in both efficacy and safety analyses. Fifty subjects treated with MIJ821 or ketamine were included in the pharmacokinetic analysis.

Primary: Change from baseline in the total score of the Montgomery Asberg Depression Rating Scale (MADRS) at 24 hrs

End point title	Change from baseline in the total score of the Montgomery Asberg Depression Rating Scale (MADRS) at 24 hrs
End point description: Efficacy. To assess change from baseline in the total MADRS score. The efficacy of MIJ821 in treatment-resistant depression will be compared to the placebo after single dose administration. MADRS is a clinician-rated scale designed to measure depression severity and detects changes due to antidepressant treatment: the test consists of 10 items, each of which is scored from 0 (item not present or normal) to 6 (severe or continuous presence of the symptoms), for a total possible score of 60. Higher scores represent a more severe condition.

End point title	Bech-Rafaelsen melancholia scale
-----------------	----------------------------------

End point description:

To assess efficacy in the melancholic subtype of depression. Depression scales are used primarily to measure changes, for example, to evaluate the efficacy of treatment with antidepressants. The Bech-Rafaelsen Melancholia Scale (BRMS) is a frequently used clinician rating scale to assess the severity of depression over the past 3 days. Each of the 11 BRMS items is operationally defined on a five-point scale (0-4); hence, the total score ranges from 0 to 44, higher scores indicating greater severity of depression.

To assess efficacy in melancholic subtype of depression. This scale is an 18 item scale, with a 6 item component capturing cognitive impairment and two motoric scales capturing psychomotor retardation (7 items) and psychomotor agitation (5 items). A cut-off score of 8 or more has been shown to differentiate melancholic from non-melancholic depression, with higher scores representing a greater probability of melancholic depression.
